

# Two-Color Calibration of the Zimmerwald SLR System

Werner Gurtner

*Astronomical Institute, University of Bern, Switzerland*

15<sup>th</sup> International Laser Ranging Workshop

15–20 October 2006

Canberra

# Contents

---

- Design of the two-color system
- Systematic biases between blue and infrared
- Source of biases
- Measures taken
- Ready for improvement of refraction correction?

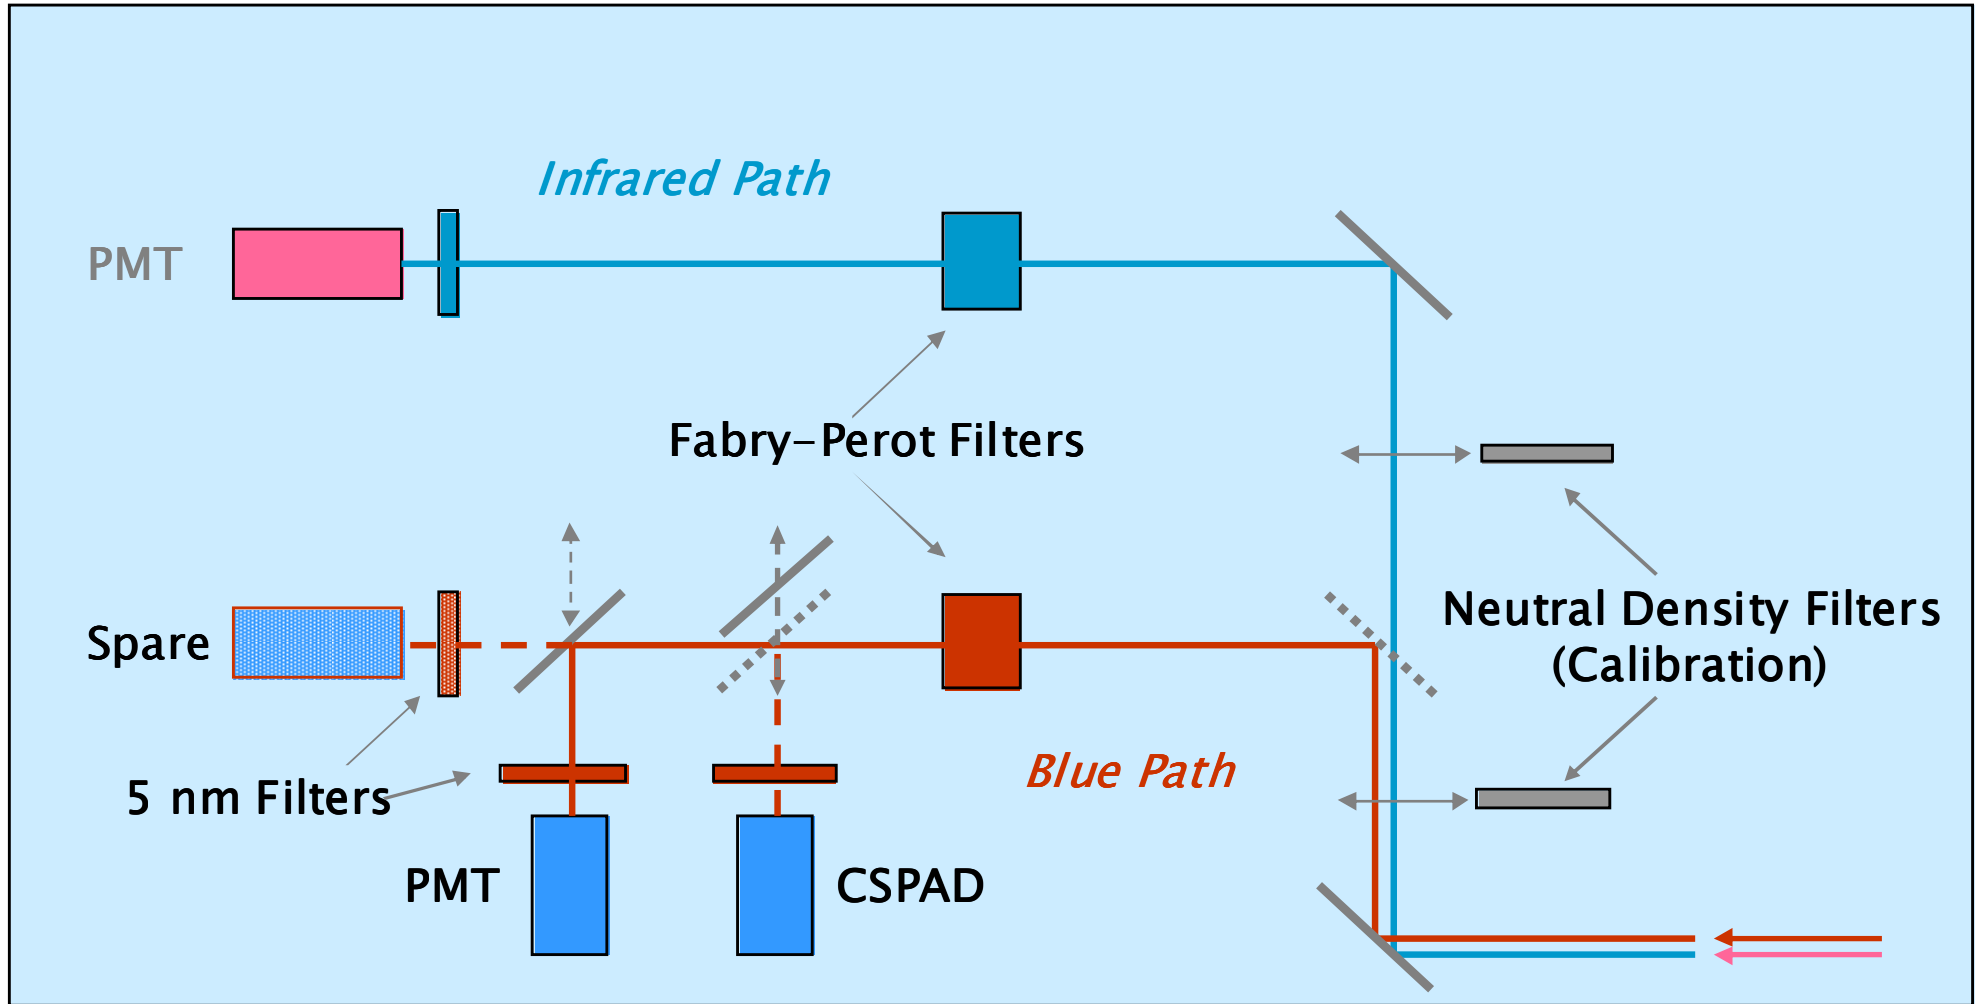

# Two-Wavelengths Design

- Coudé path optics designed for two wavelengths: 423 nm and 846 nm
- Mirror coatings in telescope optimized for the two wavelengths
- Transmit and receive paths designed for separate beam control (shutters, attenuators, filters)
- Receivers
  - Blue (423 nm): CSPAD (and Hamamatsu PMT)
  - IR (846 nm): Hamamatsu PMT

# Transmit Path

# Receiving Path

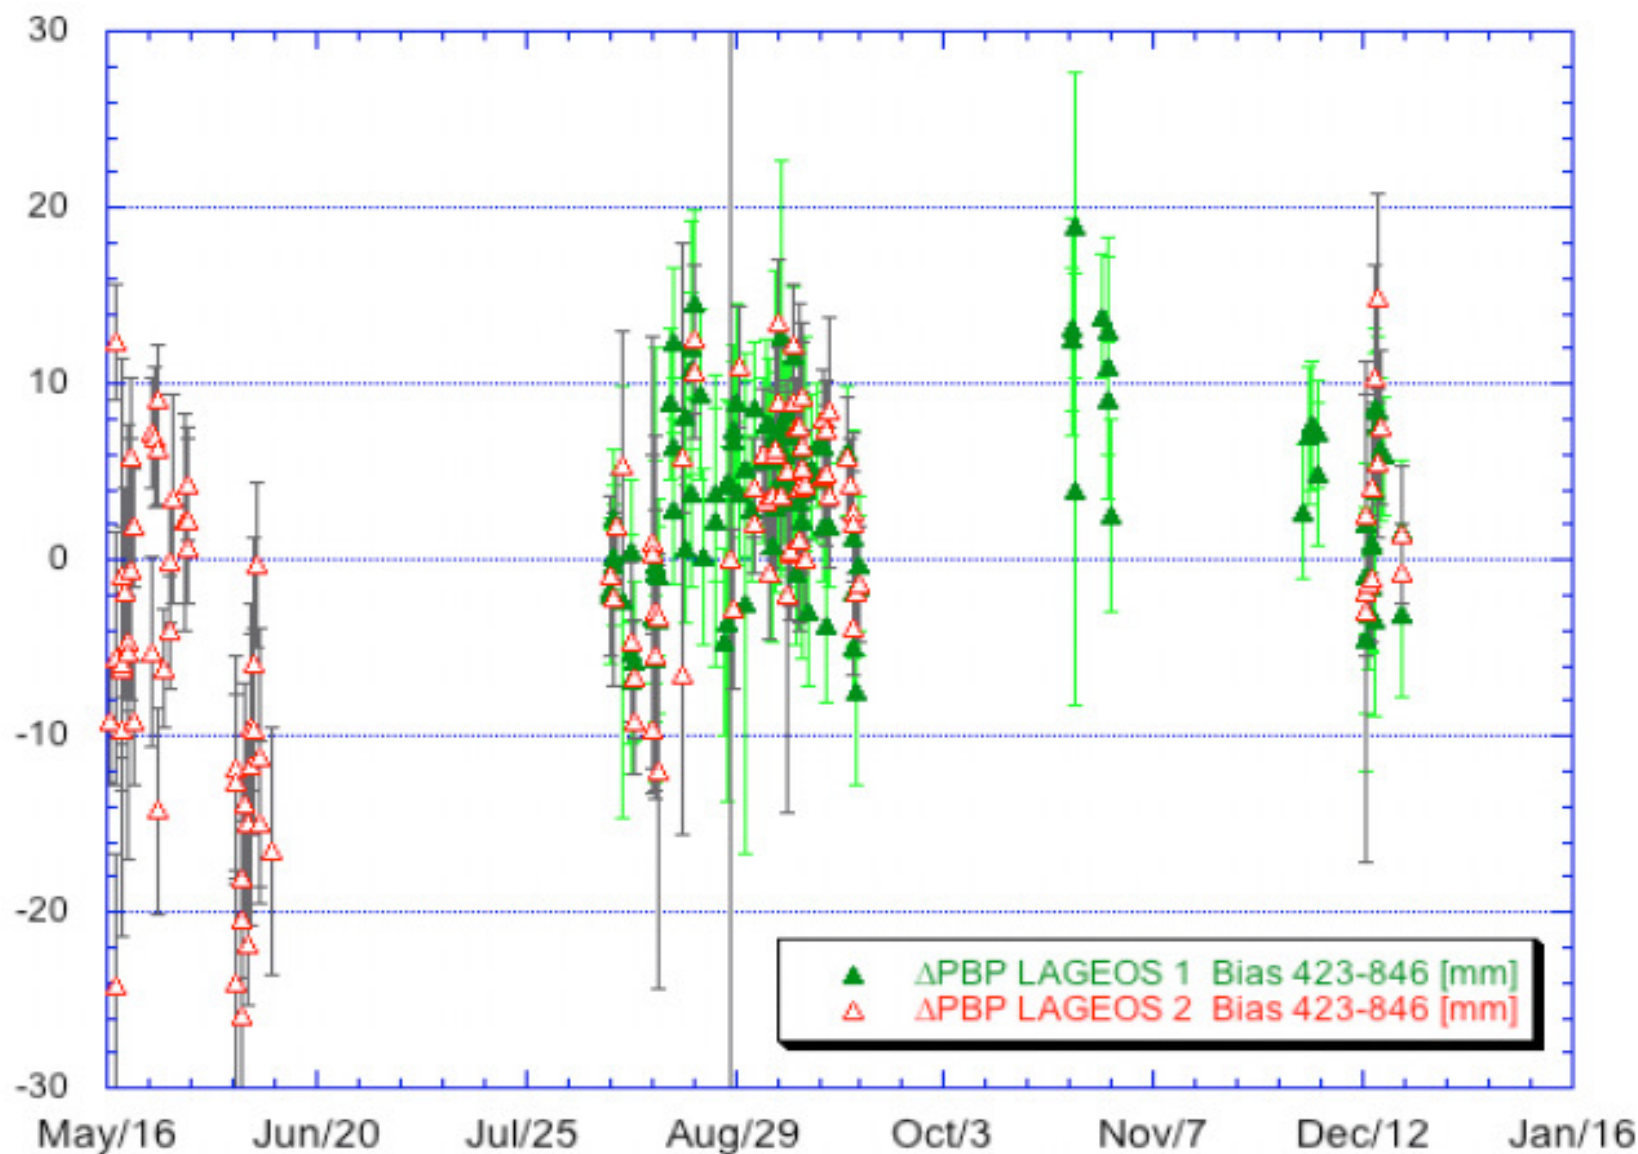

# Conclusions reported 2002

- Range biases between the two reception channels could still be in the system (a few millimeters?)
- *No systematic behavior detectable till now*
- Differences of the Marini–Murray refraction corrections at 423 and 846 nm obviously better than < 8 mm
- Is accuracy of the two wavelengths good enough for mapping function improvement?

## But ...

- Systematic and slowly (weeks – months) changing differences between calibrated ranges in blue and infrared (Marini–Murray applied)
- Up to  $\pm 2$  cm
- Pass per pass averages of pass residuals (generated during onsite np computation)
- Confirmed by analysis centers

# Pass-per-pass bias differences Blue-IR (JCET 2004)

# Improving the tropospheric refraction?

$$m_{\Delta R} = f(\lambda_i) / [f(\lambda_2) - f(\lambda_1)] m_{R2-R1}$$

Amplifying factor  $f(\lambda_i) / [f(\lambda_2) - f(\lambda_1)]$ :

**14** for  $\lambda_1 = 423 \text{ nm}$ ,  $\lambda_2 = 846 \text{ nm}$

$$m_{R2-R1} = \text{sqrt}(m_{R1}^2 + m_{R2}^2 + m_{\text{Cal}1}^2 + m_{\text{Cal}2}^2)$$

***Goal: 1 mm***

***Calibrated range difference bias-free to 0.08 mm = 0.5 ps!***

**$\rightarrow m_{R_i}$  and  $m_{\text{Cal}_i} < 1/14/2\text{mm} = 0.04 \text{ mm}!!$**
