CO₂ Condensation During South Polar Night

- Channel 1 - 3 m (BLACK)
- Channel 2 - 9 m (RED)
- Channel 3 - 27 m (GREEN)
- Channel 4 - 81 m (BLUE)

Temperature Profiles from Radio Science During Polar Winter Night

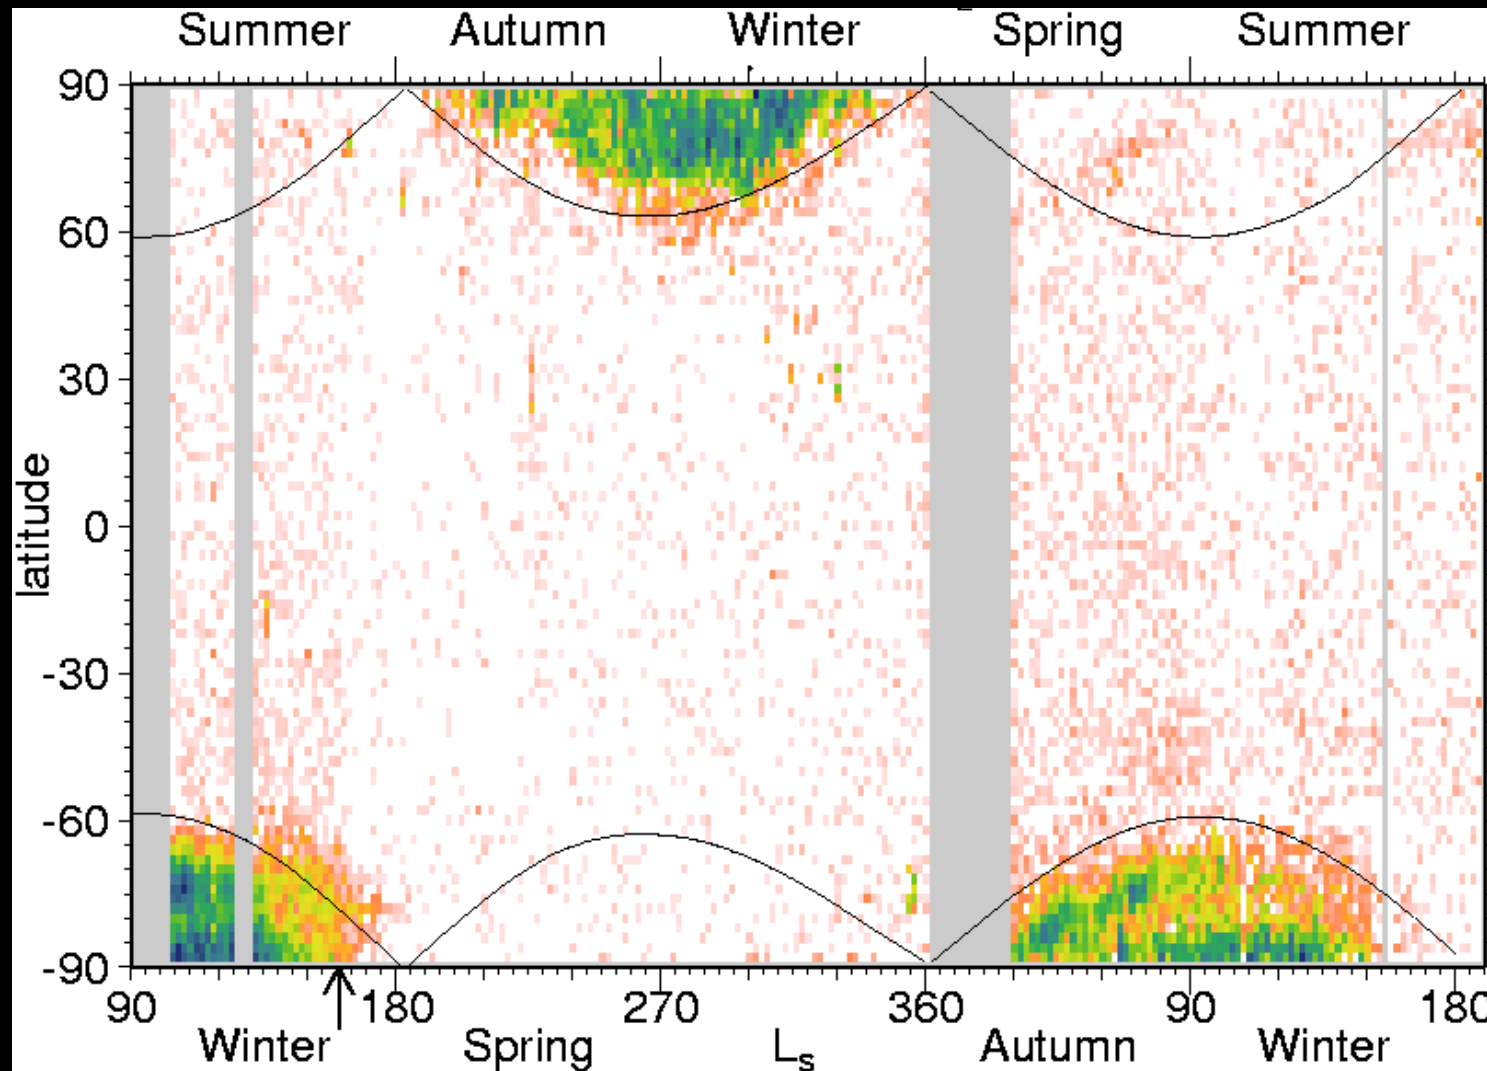

Neumann et al. [2002]

Hinson et al. [1999; 2001]

- Near-surface temperatures buffered by CO₂ ice, hovering near CO₂ saturation with a lapse rate of -0.85 K km⁻¹.
- CO₂ clouds nucleate spontaneously at 2 K below saturation, possibly as snow.
- Equilibrium restored as clouds release latent heat and lower P_{CO₂}. Neumann et al. [2003]

Cloud Density Averaged by Latitude and L_s

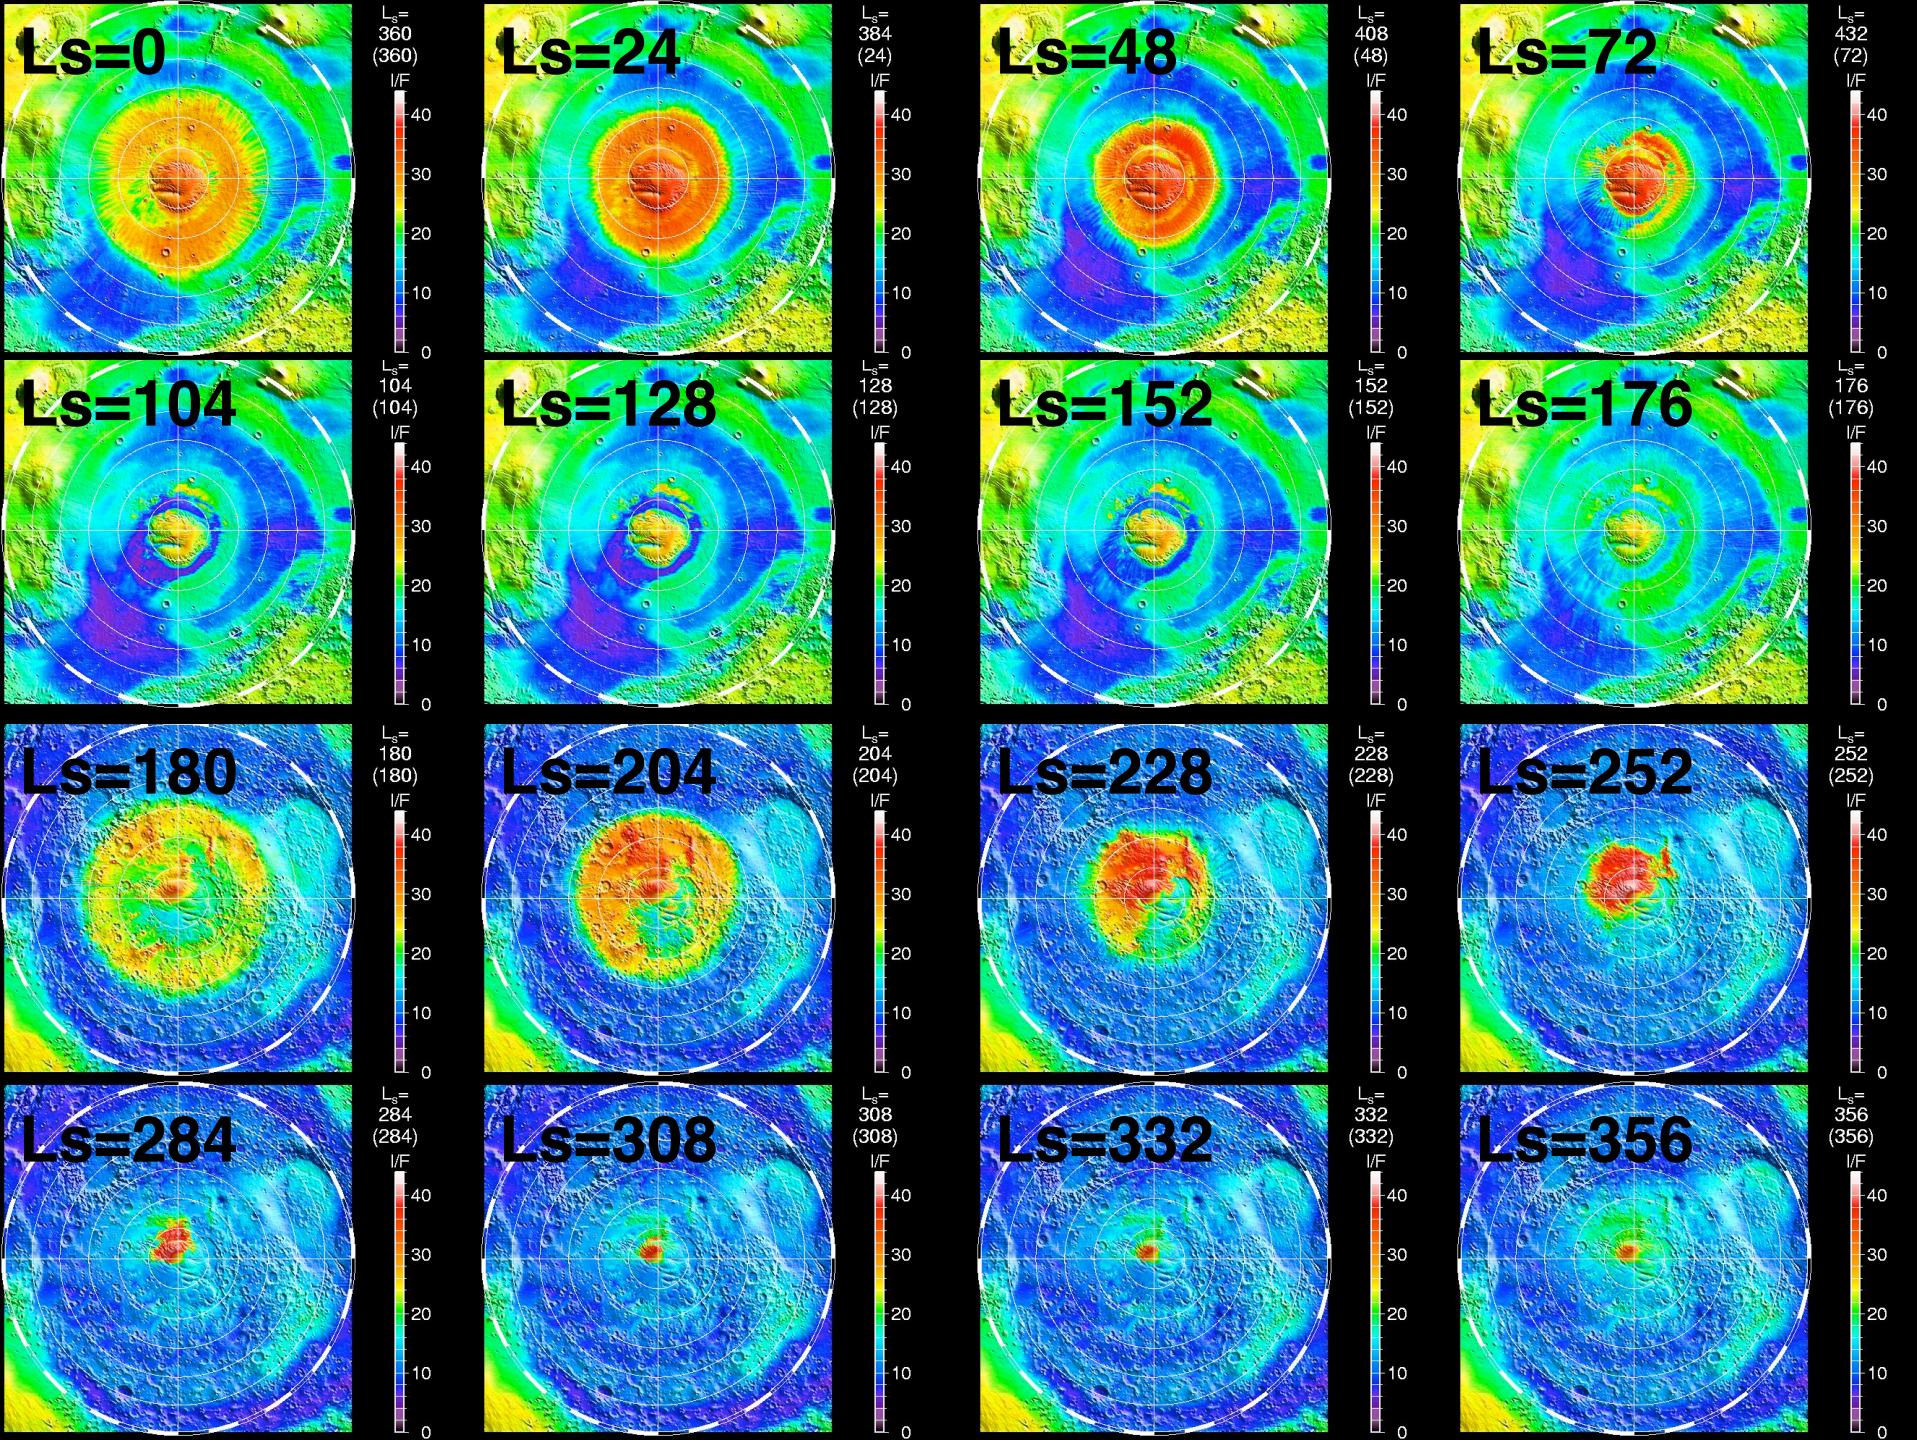

Noise level varies with threshold and laser output.

Dark curves show limits of along-track day/night terminator.

Approach

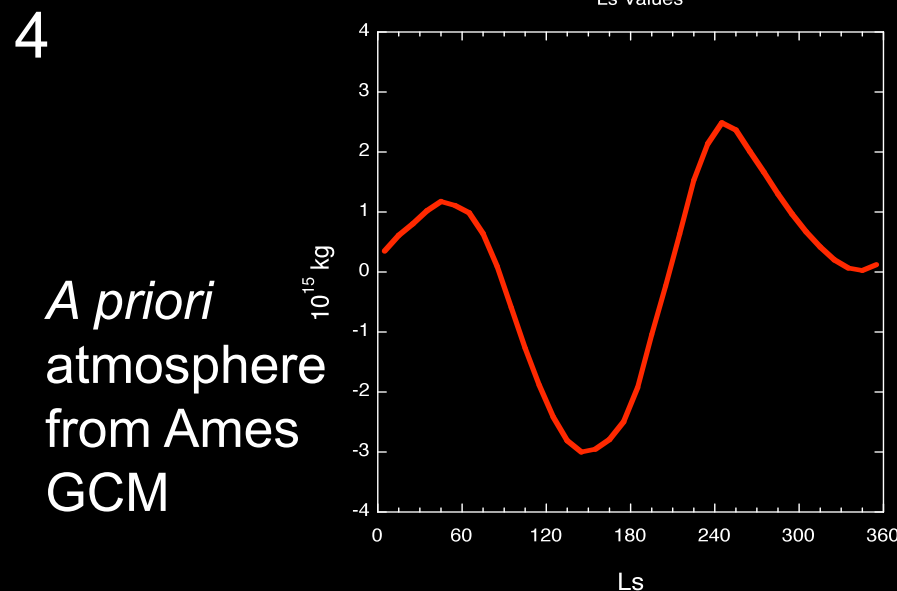

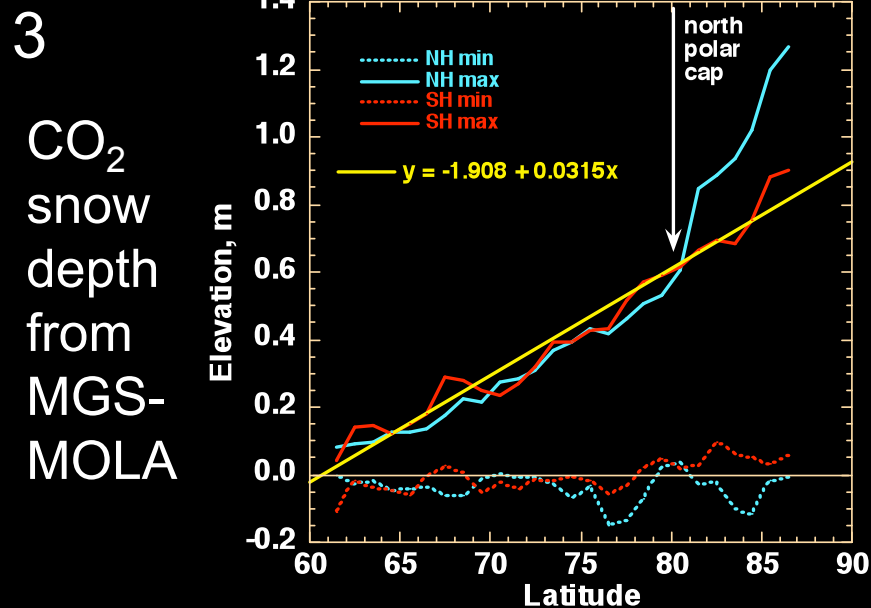

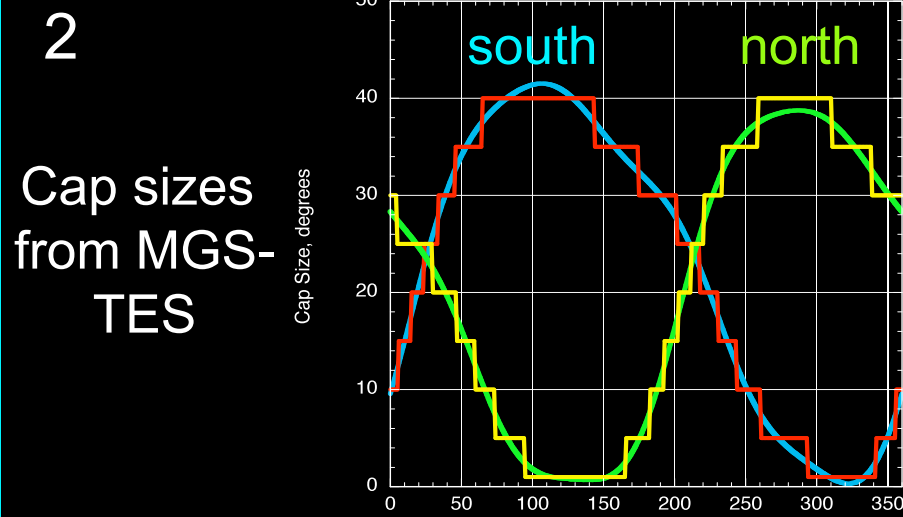

- Model seasonal CO₂ mass exchange between Martian atmosphere and polar caps.
- Treat season caps as “mascons” and solve for mass within specified geometric shapes every 5 days.
- Use Mars Global Surveyor (MGS) thermal emission (TES) and altimetry (MOLA) data to model latitudinal extent of condensed CO₂ and MOLA altimetry to approximate the vertical dimension of shape of anomalous masses.
- Estimate mass of material exchanged with atmosphere from perturbations of orbit of MGS spacecraft from X-band tracking data.

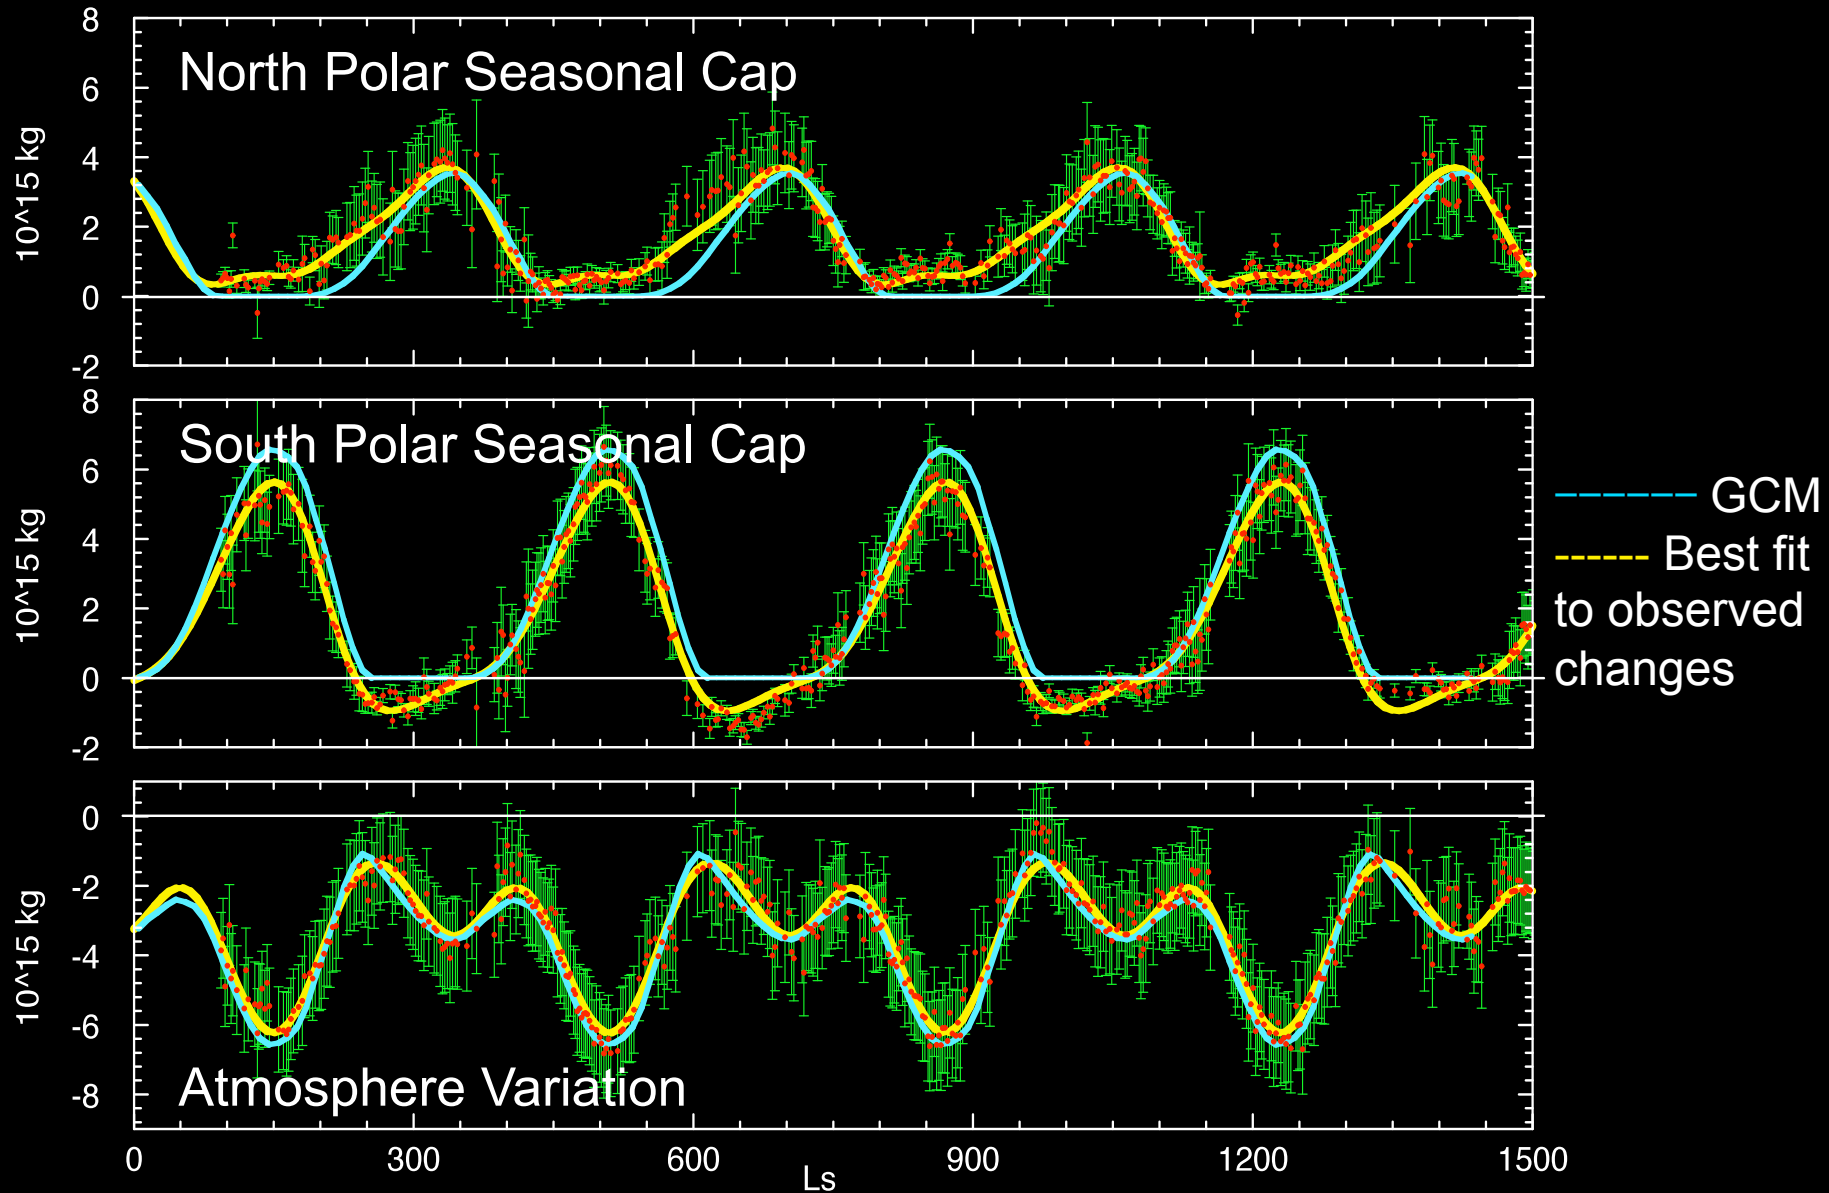

Details

- Model season polar caps, and seasonal variations in atmospheric mass.
- Treat seasonal polar caps as cones that overlie topography with radial extent coming from TES bolometric observations and elevation from MOLA.
- Model variable component of seasonal atmospheric mass as a surface layer overlaying the topography.
 - *Model 1* assumes atmosphere is a surface layer between the polar caps.
 - *Model 2* assumes atmosphere is a global surface layer.

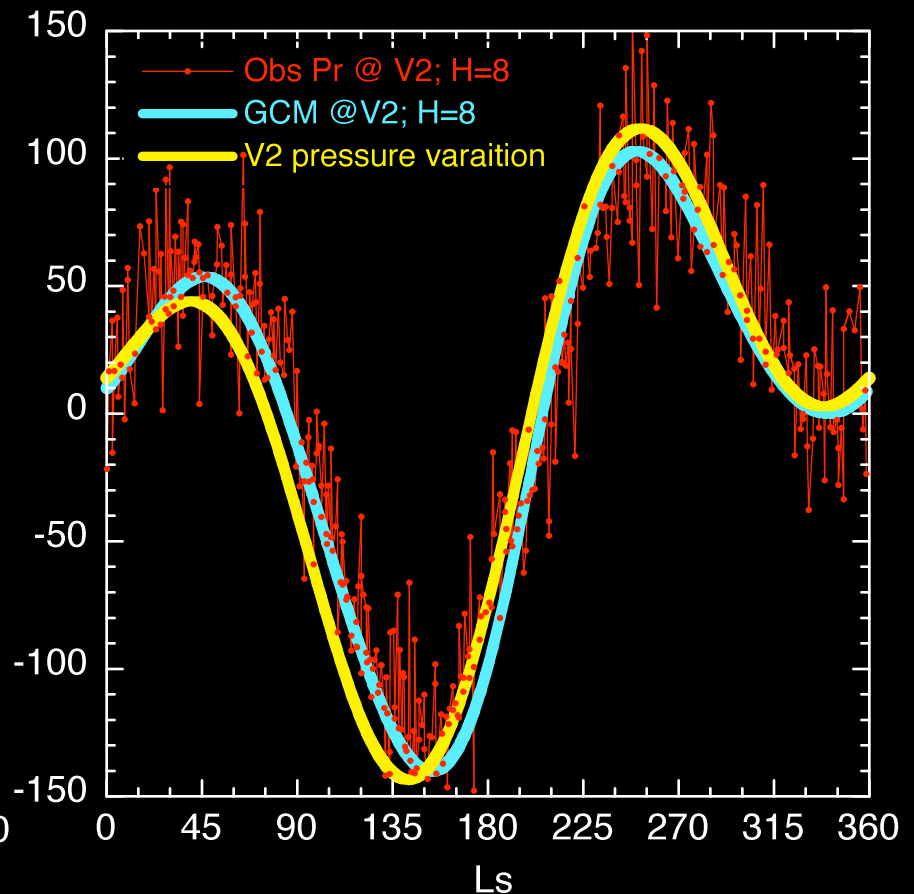

Simple Model of Mars' Seasonal Polar Caps of Mars

Seasonal Mass Changes over 4 Mars Years

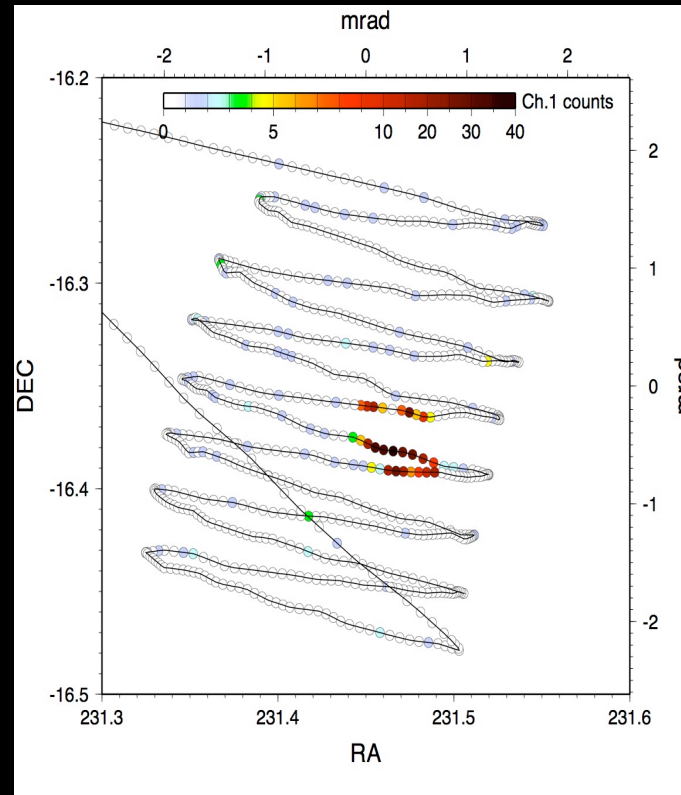

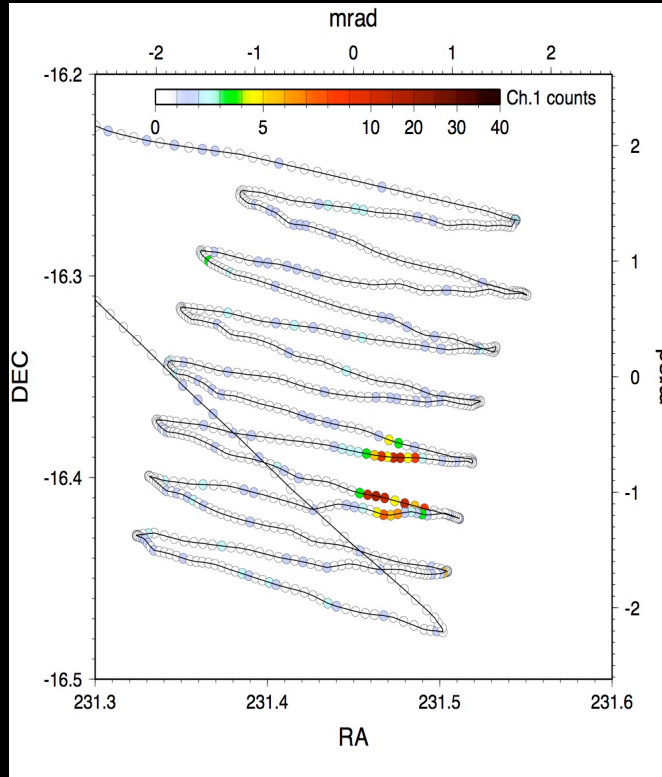

Mean Atmospheric Pressure @ V1 and V2

→ Mean atmospheric pressure derived from global variation in atmospheric mass and used to infer pressure at the two Viking lander sites taking into account their altitudes.

The Future

Abshire et al. [2008]

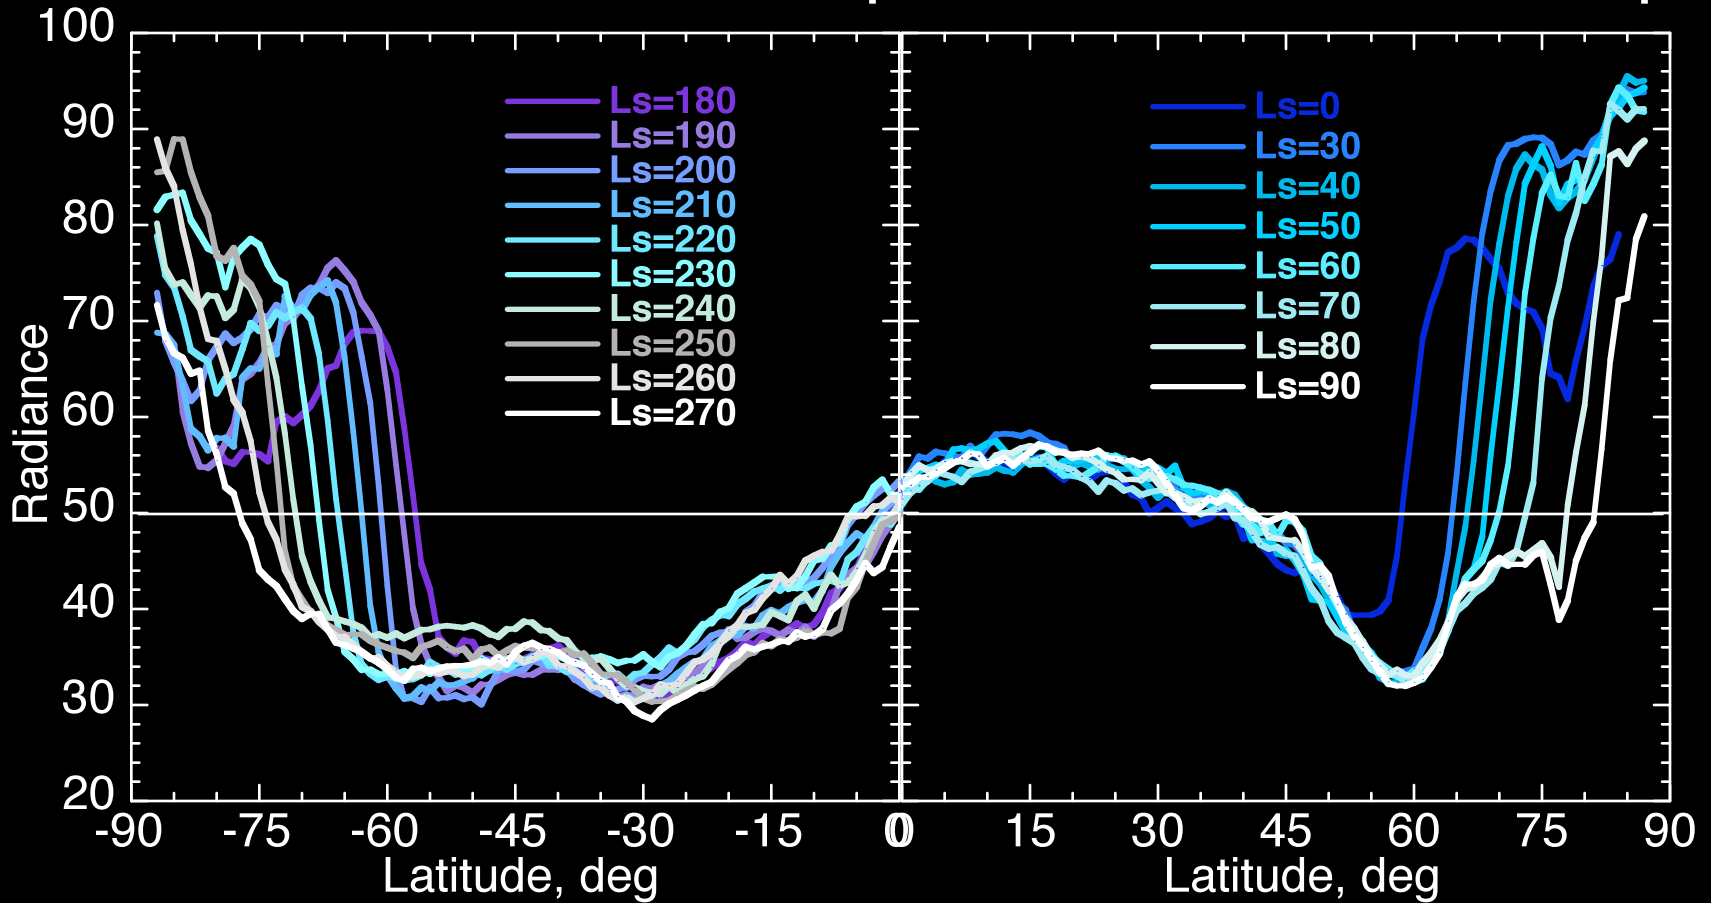

- Laser ranging would improve s/c position & ephemeris of Mars.
 - reduce systematic errors ideally enabling detection of subtle longterm effects.

Summary

- Analyzed >4 Mars years (~8 Earth-years) of X-band tracking data from MGS.
- Excellent agreement on magnitude of signal with NASA/Ames GCM, but differences also exist:
 - more rapid accumulation in Fall season
 - non-zero “summer” mass
- MRO is extending time series and will eventually reduce systematic errors in gravity field recovery, but challenge to merge different spacecraft observations.
- Goal is to detect interannual (decadal) variability in seasonal mass exchange.
 - laser ranging would help

Recession of SP Seasonal Icecap Recession of NP Seasonal Icecap

Passive radiometry data provides variation in radiance with latitude averaged over all longitudes.

The edge of the cap is taken to have a radiance of 50 and used to monitor the size of each seasonal icecap.
